## Abstract

1 In this work, we propose a novel framework  
2 for image segmentation guided by visual prompt-  
3 ing which leverages the power of vision founda-  
4 tion models. Inspired by recent advancements in  
5 computer vision, our approach integrates multi-  
6 ple large-scale pretrained models to address the  
7 challenges of segmentation tasks with limited and  
8 sparsely annotated data interactively provided by a  
9 user. Our method combines a frozen feature extrac-  
10 tion backbone with a scalable and efficient proba-  
11 bilistic feature correspondence (soft matching) pro-  
12 cedure derived from Optimal Transport to couple  
13 pixels between reference and target images. More-  
14 over, a pretrained segmentation model is harnessed  
15 to translate user scribbles into reference masks and  
16 matched target pixels into output target segmen-  
17 tation masks. This results in a framework that  
18 we name *Softmatcher*, a versatile and fast training-  
19 free architecture for image segmentation by visual  
20 prompting. We demonstrate the efficiency and scal-  
21 ability of *Softmatcher* for real-time interactive im-  
22 age segmentation by visual prompting and show-  
23 case it in diverse visual domains including techni-  
24 cal visual inspection use cases.

## 1 Introduction

26 Foundation Models ushered in a significant shift in how ma-  
27 chine learning models are developed and deployed, pivoting  
28 from a paradigm centered on training use case-tailored mod-  
29 els on task-specific data to a paradigm where single generalist  
30 models are pretrained on diverse large-scale data, then fine-  
31 tuned for a wide range of tasks [Bommasani *et al.*, 2022].  
32 Specifically in computer vision, models such as SAM [Kir-  
33 illov *et al.*, 2023], CLIP [Radford *et al.*, 2021], and self-  
34 supervised backbones such as DINO [Caron *et al.*, 2021] and  
35 DINOv2 [Oquab *et al.*, 2023] have unlocked powerful and  
36 versatile visual functionalities like object detection, semantic  
37 segmentation and expressive embeddings that are at the core

of a multitude of diverse applications. In particular, the pos-  
sibility of using and combining these models in novel ways  
to address specific challenges in applied computer vision has  
been a topic of recent interest, including as a means to design  
new workflows in technical domains such as visual inspection  
(see e.g. [Rigotti *et al.*, 2023]).

In this work we take inspiration from the recent advance-  
ments driven by the approach of compositionally combining  
multiple Foundation Models to address sophisticated com-  
puter vision tasks. Specifically, we focus on the problem of  
image segmentation, which is a fundamental task in computer  
vision with a wide range of applications, including medi-  
cal imaging, autonomous driving, and visual inspection, with  
a particular focus in developing a human-computer interac-  
tion workflow to facilitate open-world segmentation of im-  
ages by visual prompting through sparse user annotations.  
For that we largely build upon a previous architecture named  
*Matcher* which was designed to perform training-free few-  
shot segmentation using *in-context examples* by means of off-  
the-shelf vision Foundation Models [Liu *et al.*, 2023]. Our  
framework enhances this approach’s interactivity in two cru-  
cial ways: 1) we integrate a pretrained segmentation model  
to translate user scribbles on a representative sample of the  
object class to be segmented into reference masks which are  
then passed to the few-shot segmentation architecture; 2) we  
develop a scalable probabilistic feature soft-matching proce-  
dure whose efficiency and low-latency allows us to embed  
few-shot segmentation in a real-time interactive workflow.

## 2 Related Work

The **Segment Anything Model (SAM)** [Kirillov *et al.*, 2023]  
has popularized the prompting paradigm in computer vision  
by enabling fine-grained image segmentation through inter-  
active prompts in the form of points and/or bounding boxes.

Both **Visual Prompting via Inpainting** [Bar *et al.*, 2022]  
and **SegGPT/Painter** [Wang *et al.*, 2023] presented visual  
prompting models trained on few-shot image segmentation  
datasets. These models operate on a reference image and cor-  
responding segmentation masks, and generate a segmentation  
mask for a target image based on the reference.

[Zhang *et al.*, 2023] introduced a training-free method for  
one-shot segmentation leveraging pretrained image encoders  
in conjunction with SAM. The labeled pixels within the an-  
notated mask on a reference image are assigned to pixels on

\*Lead authors

†PIs, corresponding authors: {abt, mrg}@zurich.ibm.com

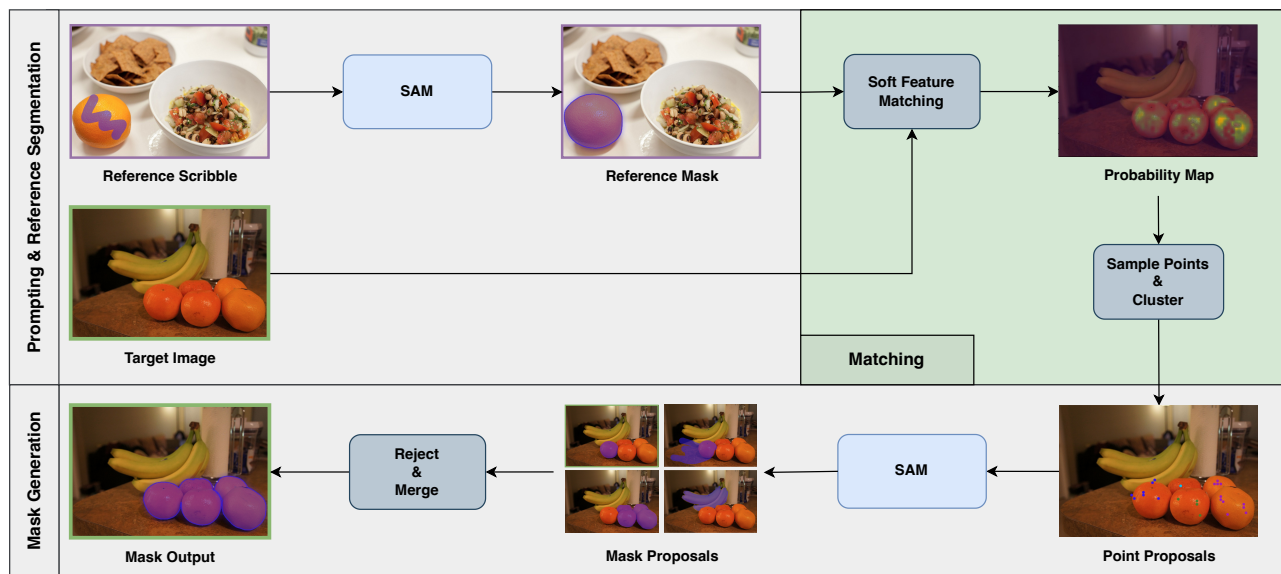

Figure 1: **Visual Prompting Framework:** 1) *Prompting & reference segmentation:* Coarse user annotations (scribbles) are converted to reference segmentation mask using SAM. 2) *Matching:* Image features are extracted using DINOv2 from reference and target images. The feature patches from within the reference mask are matched to all patches in the target through our probabilistic matching procedure, resulting in a probability map over target images. This is sampled to obtain sample points which are then clustered. 3) *Mask generation:* For each cluster the respective points are passed to SAM to generate mask proposals. Each mask proposal is scored and discarded based on SAM-predicted IOU or merged into the final output mask.

81 target images thanks to a cosine similarity matrix of their cor-  
 82 responding encoded patches. The target patch of maximum  
 83 similarity is then utilized by SAM to generate a segmentation  
 84 mask for the target object.

85 [Gupta and Kembhavi, 2022] presented a neuro-symbolic  
 86 approach for solving complex visual tasks given natural lan-  
 87 guage instructions by leveraging the in-context learning ability  
 88 of LLMs to generate modular programs that combine pre-  
 89 trained models leveraging their *compositionality*, a feature  
 90 that has received recent interest for enabling flexible gener-  
 91 alization (see e.g. [Ito et al., 2022]).

92 [Liu et al., 2023] introduced **Matcher**, an approach that  
 93 uses a bidirectional matching procedure to match encoded  
 94 reference and target image patches using the Hungarian algo-  
 95 rithm, an accurate but slow assignment algorithm with worst-  
 96 case complexity cubic in the size of the problem [Crouse,  
 97 2016]. Similarly to [Zhang et al., 2023], one-shot (or few-  
 98 shot) segmentation is implemented by assigning annotated  
 99 encoded pixels on reference images to encoded target pixels,  
 100 which then serve as prompts for SAM to produce segmen-  
 101 tation mask proposals on the target images. The set of mask  
 102 proposals are finally scored and either accepted or rejected.

103 [Janouskova et al., 2023] proposed a framework for model-  
 104 assisted labeling of visual inspection defects through an inter-  
 105 active annotation process leveraging gradient-based explain-  
 106 ability to improve the efficiency of the provided labels.

### 107 3 Visual Prompting Framework

108 **System architecture.** Figure 1 presents our **Sofmatcher**  
 109 framework for interactive image segmentation guided by vi-  
 110 sual prompting on a reference image. This consists of 3 steps:

111 **1) Prompting & reference segmentation**, where a user pro-  
 112 vides scribbles on the reference image indicating the object  
 113 class to be labeled on the target images, and where the scrib-  
 114 bles are used as sparse prompt for SAM which then is used to  
 115 output a reference mask; **2) Matching**, where *soft probabilis-  
 116 tic matching* (detailed below) outputs a probability map over  
 117 pixels of each target image quantifying their match to pix-  
 118 els in the reference mask; points are then sampled from the  
 119 probability map, clustered and used for **3) Mask generation**,  
 120 where clustered points are used as sparse prompts to SAM to  
 121 generate mask proposals; these are filtered based on SAM’s  
 122 IoU predictions and aggregated into the mask output.

123 The key innovations of our framework compared to pre-  
 124 vious approaches like **Matcher** [Liu et al., 2023] are aimed  
 125 at producing an architecture that is amenable to being em-  
 126 bedded in an interactive object segmentation workflow where  
 127 users can provide visual prompts by coarsely annotating ref-  
 128 erence images through scribbles and interact in real-time with  
 129 the resulting segmentation masks, possibly by correcting or  
 130 complementing them with additional annotations.

131 Our first innovation for this is the **Prompting & reference  
 132 segmentation** step in Fig. 1, which, while conceptually sim-  
 133 ple, provides a way for the user to directly and intuitively  
 134 prompt the segmentation pipeline with *coarse visual prompts*  
 135 (*scribbles*) instead of requiring detailed segmentation masks.

136 Our second major innovation is a computationally efficient  
 137 version of the **Matching** step in Fig. 1, and was dictated by  
 138 the requirement of low-latency segmentation and the obser-  
 139 vation that feature matching procedure used in the past like  
 140 the Hungarian algorithm (see e.g. [Liu et al., 2023]) display  
 141 a worst-case computational complexity that scales *cubically*

Figure 2: **Relative timing of different matching procedures** computed on 1 CPU core on a Dual AMD EPYC 7003/7002 Series Processors, assuming a featurization based on a VIT encoder with patch size of 14, feature size of 768.

| FSS-1000  | Matcher     | SM (ours)  | SM RFF (ours) |
|-----------|-------------|------------|---------------|
| one-shot  | <b>87.0</b> | 85.5 ± 0.7 | 85.9 ± 0.6    |
| five-shot | <b>89.6</b> | 87.1 ± 0.1 | 87.1 ± 0.3    |

Table 1: **Few-shot evaluation on FSS-1000:** We compare performance in terms of IOU of Matcher with our Softmatcher (SM) and Softmatcher RFF (SM RFF) methods on FSS-1000.

182 tive objects in one or more reference images with scribbles. 183 Given the improved computation complexity, our method al- 184 lows the user to iterate in real-time with the segmentation out- 185 puts, adding additional scribbles on additional references to 186 improve segmentation in case the model missed something, 187 resulting in an intuitive and seamlessly interactive workflow.s

188 **Deployed service and front-end.** The interactive web in- 189 terface is designed to provide seamless interaction between 190 the user and the Softmatcher pipeline. It consists of a front- 191 end built with Angular, a Python API back-end, and an in- 192 ference service using Torch Serve. Users add scribbles to 193 any image to mark objects of interest. The visual prompt- 194 ing pipeline then highlights similar objects with precise seg- 195 mentation masks the target images. If the user is not satisfied 196 with the initial results, they can refine the outputs by itera- 197 tively adding or deleting scribbles. Alternatively, instead of 198 adding more scribbles, users can add more prompts by con- 199 verting output segmentation masks from a previous run into 200 reference masks. These reference masks will skip step 1 of 201 the pipeline (see Fig. 1). The system also allows for scribbles 202 to be classified into different categories, enabling the creation 203 of segmentation masks for multiple classes.

204 The process of repeatedly adding and adjusting scribbles 205 provides users with a deeper understanding of how the model 206 operates. By understanding the model’s capabilities and lim- 207 itations, users learn to collaborate with the model more ef- 208 fectively, leading to better outcomes. We’ve also started to 209 enhance our framework’s interactivity with vision-language 210 models like CLIP, enabling the use of text prompts in addi- 211 tion to reference scribbles. This opens up the possibility to 212 combine visual and text prompts to refine masks mutually and 213 address scenarios where scribbling alone is not be enough.

214 **Demonstration.** We illustrate how users typically engage 215 with our web interface and the visual prompting pipeline 216 through three sample projects. The first two projects illustrate 217 a general use case on everyday objects, while the third shows 218 a domain-specific proprietary defect detection dataset. Our 219 demonstration covers the interactive process of adding scrib- 220 bles to images, executing the pipeline to receive segmentation 221 masks, and then enhancing the results by adding additional 222 scribbles. Furthermore, we showcase the capability for users 223 to process images with references from various classes.

## Acknowledgments 224

225 We would like to thank Trafikverket for their collaboration, 226 specifically for the collection of image data of civil infras- 227 tructures. We are also grateful to Youssef Mroueh for insight- 228 ful discussions. This work is partly funded by the European 229 Union’s Horizon Europe research and innovation programme 230 under grant agreements No. 101070408 (SustainML).

142 with image sizes (number of patches) [Crouse, 2016], mak- 143 ing them unpractical for an interactive workflow. Instead 144 of using (Hungarian) bipartite matching based on the cosine 145 similarity between reference features and target features we 146 opt for an Optimal Transport (OT) approach based on the 147 quadratic cosine similarity matrix as cost matrix. While very 148 related, this method allows us to motivate a sequence of ap- 149 proximations for an efficient implementation of the match- 150 ing procedure: we first introduce an entropic regularization, 151 then consider the case of large regularization limit where 152 the solution to the OT problem converges to the geomet- 153 ric mean of softmaxed cosine similarity maps between indi- 154 vidual reference features and target feature maps (where the 155 averaging is conducting across reference features) [Dognin 156 *et al.*, 2019], an operation which only has *quadratic* com- 157 plexity in the number of image patches complexity and re- 158 sults in our *Softmatcher* procedure. Moreover, it affords 159 an even more scalable implementation by approximating the 160 softmax computation of reference-target feature similarities 161 through Random Fourier Features [Rahimi and Recht, 2007; 162 Choromanski *et al.*, 2020], which we call *Softmatcher RFF*.

163 Figure 2 compares the timing of matching reference and 164 target image features with the Hungarian algorithm, com- 165 pared to our proposed soft matching methods as a function 166 of image size assuming a featurization based on a VIT en- 167 coder with patch size of 14, feature size of 768. *Softmatcher* 168 is around 6x faster than the Hungarian algorithm at image size 169 448, and this discrepancy quickly increases with image size, 170 due to its better computation complexity scaling. *Softmatcher* 171 *RFF* is slightly faster and displays even better scalability.

172 We evaluate our visual prompting pipeline on FSS-1000 173 [Li *et al.*, 2020], which consists of 1000 object classes with 174 pixel-wise annotations. FSS-1000 contains many objects not 175 part of any previously annotated dataset (e.g., tiny daily ob- 176 jects, merchandise, and cartoon characters). As this disentangles 177 previous knowledge from pretrained models to a certain 178 degree, it lends itself well as a few-shot benchmark.

179 We integrate this improved matching pipeline into an inter- 180 active Visual Prompting platform that allows users to segment 181 objects classes of interest by merely highlighting representa-
